

## Bugometer

If it is your intent to excel in a bug hatch, you must know the species of the insect, the color, and the exact size. Hatches must be matched perfectly to entice a fish to eat your fly. Species and color can be determined quite easily by simply picking up the bug for a thorough examination. Where we fail most often is in the size of the insect. A good fishing buddy of mine, Troy Pearse, created a measuring device to solve the problem of size. It is called a Bugometer. It can be used to precisely measure body length of a bug and instantaneously equate it to a hook size. This is a photo of a Streamside Reference Bugometer (which attaches to a zinger on your vest. It is waterproof, scratchproof, UV coated, and the size of a credit card.) Notice measurement from head to end of abdomen *only*. Do not include wings, antenna, or tail. These are photos of the Bugometer doing its job.

Bugometer (Not Actual Size)

Fall Caddis Size 8

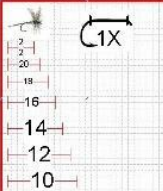

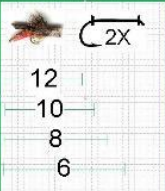

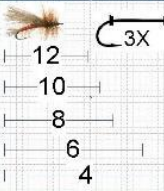

Hopper Size 4

Midge Size 20

The Bugometer comes with a second measuring device called the *Benchside Reference*. I have several of them laminated and I keep them in my fly tying room. I often bring home insects from the river to recreate at the vise. The benchside measures these bugs in millimeters and the chart converts that measurement to hook size. It's a quick, easy way to derive the exact hook size on which a bug should be tied. Appendix B displays a Benchside and Streamside Reference in actual sizes.

Troy wrote an awesome article entitled "Size Matters" in the June 2011 *American Angler* magazine explaining the importance of the Bugometer. (Back issues of *American Angler* are available at: <http://americanangler.com/contact-us/contact-us>)
